# YUKON HYDROELECTRIC POWER PLANNING DIRECTIVE CRITERIA

In early 2013, Yukon Government issued the Yukon Hydroelectric Power Planning Directive to Yukon Development Corporation (YDC).

The Directive tasks YDC to plan the development of one or more hydroelectric projects, to ensure together with supporting renewables and to the minimum extent feasible non renewable sources of electrical power, an adequate and affordable supply of reliable and sustainable electrical power in Yukon.

" Evaluates the expected growth in residential, commercial and industrial demand for electrical power in Yukon."

"Plans for scalability, so as to allow for the increase of energy supply over time to meet projected demand growth."

" Assess the project's financial needs and risks, and evaluate options for project financing and financial risk mitigation."

Determine the anticipated positive and negative socio-economic and environmental effects of the project, and develop specific means of maximizing its benefits, minimizing its adverse effects and mitigating any unavoidable negative impacts.'

"In respect to the effects have particular regard to the impacts on and opportunities for, the First Nation or First Nations in whose traditional territory the project may be located."

**Engage with First Nations to explore options for project** locations as well as opportunities for partnership in project planning and execution."

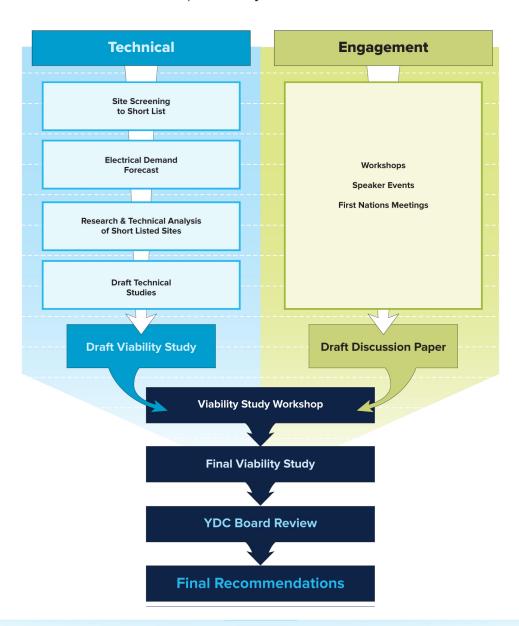

Consider one or more specific possible locations for the project, taking into consideration the above criteria as well as proximity to the existing and expected future customer base."

# **PROJECT PROCESS**

Input, comments and feedback will be gathered throughout the course of the year as technical results are shared. Feedback will be compiled in the Next Generation Hydro Discussion paper that will be presented to the Yukon Development Corporation (YDC) board together with a summary of all technical work - the Next Generation Hydro and Transmission Viability Study. The YDC board will review both documents to develop a recommendation for one or more potential hydro sites.

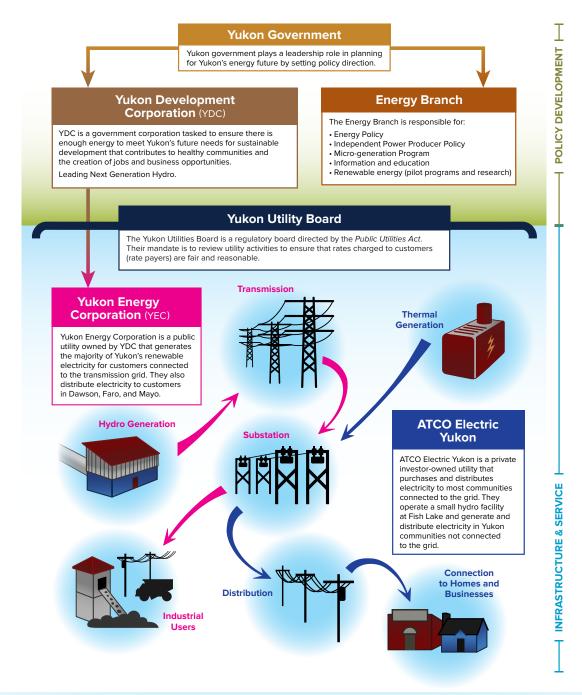

# YUKON'S ENERGY PARTNERS

Several key players have a role in ensuring that Yukon's electricity supply remains abundant, reliable, and cost effective for generations to come. Read more about each key organization and their role in the big picture.

# **GLOSSARY OF TERMS**

Biomass: Energy resources from organic matter, including wood, agriculture waste, and other living material that can be burned to produce electricity and heat.

Capacity (Demand): The supply (or consumption) of electrical power at a given instant in time. Usually measured in watts (W), kilowatts (kW) or megawatts (MW) depending on context. The annual peak demand is a key factor in sizing power lines and generators.

Kilowatt (KW) = 1000 watts

Megawatt (MW) = 1000 KW

**Gigwatt Hours (GWh)** = 1000 GW

Climate Change: A change in the average weather that a given region experiences. Climate change on a global scale includes changes to temperature, shifts in wind patterns, and changes to precipitation (from Climate Change Action Plan).

**Demand Side Management (DSM)**: The attempt to reduce overall electrical consumption at customer sites via initiatives, rate structures and or codes/standards. Demand side management, when used during peak demand periods, is useful to delay or avoid upgrading power infrastructure.

Dispatcheable Generation: Refers to sources of electricity that can be dispatched at the request of power grid operators; that is, generating plants that can be turned on or off, or can adjust their power output on demand. Also called "firm" energy.

**Distribution Lines:** Conductors strung on overhead structures or placed underground that deliver electric power from substations to user sites (e.g. homes, shopping centres, mines).

Electrical Grid or "The Grid": The connected network of transmission lines, substations and distribution lines that brings power from sources (e.g hydro plants, wind turbines, diesel generators) to users (homes, businesses and industrial projects).

**Energy:** The supply (or consumption) of electrical power over a period of time. Usually measured in kilowatt-hours (kWh) for residential usage or gigawatt-hours (GWh) for regional/territorial usage. The annual energy supply must at least cover the annual energy consumption.

Kilowatt hour (kWh) - amount of energy used or produced in an hour

Example: Energy is power x time (1 MW or 1000 kW x 8760 hours per year = 8.76 GWh)

Example: a 100 watt light bulb 10 hours consumes one kWh of electricity (100 watts x 10 hours = 1000 watts per hour (Wh) or 1 kWh)

**Generation:** The source of electrical power be it hydro, wind, solar, or thermal (fossil fuel).

Generation Resource: The primary energy source that is converted to electrical power. Common generation resources include hydro, wind, solar, or thermal (e.g. natural gas, coal or diesel).

Geothermal: The use of heat from the earth to generate electricity or provide space heating and cooling.

**Hydropower:** A form of electrical power generated by converting the kinetic energy of moving water to electricity using a turbine. The capacity of the resource is influenced by the flow and elevation drop (head).

Independent Power Producer (IPP): An energy producer who generates electricity for sale to utilities or consumers such as the general public, businesses or industries.

**Intermittent Energy:** Any source of energy that is not continuously available due to some factor outside direct control (i.e wind blowing, or sun shinning).

**Load:** The electrical energy required to power homes, businesses and industrial processes. Sometimes referred to as demand.

**Load Profile:** A visualization of load (energy demand) over time.

**Medium Hydro:** A category of hydropower generation that typically has a peak capacity between 10 MW and 100 MW.

Micro Hydro: A category of very small hydropower generation that typically has a peak capacity of less than 100 kW and uses the natural flow of water.

**Net Metering:** When electricity consumers who own small, renewable energy generators such as wind or solar can receive a credit for a portion of the electricity they generate.

Resource Capacity: The quantity of a particular energy resource. It is usually reported on a site-by-site, regional or territorial basis in both capacity (MW) and energy (GWh) terms

Renewable Energy: Energy that comes from sources renewed on an ongoing basis through natural processes. Examples include sun, wind, wood, flowing water, or relatively warm ground, air or water temperatures (from Climate Change Action Plan).

Run of River Hydro: Is a type of hydroelectric generation where little or no water storage is used.

Small Hydro: A category of hydropower generation that typically has a peak capacity of less than 10 MW and requires some form of weir in the stream or river.

Sustainable Electricity: Is about pursuing innovative business strategies and operating activities that meet the needs of members, stakeholders and the communities in which we operate, while protecting and enhancing the legacy we leave for future generations (from Canadian Electricity Association).

Storage Hydro: Is a type of hydroelectric generation where a storage reservoir is created to store water to accommodate fluctuating river flows.

Sustainable Development: Beneficial socio-economic change that does not undermine the ecological and social systems upon which communities and societies are dependent (Umbrella Final Agreement).

The Public Utilities Act: Among other things defines a public utility as producing, generating, storing, transmitting, selling, delivering or furnishing electricity or gas to or for the public or a corporation for compensation. The act also defines the role of the Yukon Utilities Board (YUB) and the regulation of public utilities via a franchise. There are several Orders in Council that direct the YUB as well. One is the Rate Policy Directive (1995) O.I.C. 1995/090 that ensures ATCO Electric Yukon and Yukon Energy Corporation cannot charge customers different rates and all Yukon residential customers who use 1000 kWh or less per month are charged the same no matter their location in Yukon.

Transmission Lines: Conductors strung on overhead structures (wood pole or lattice steel towers) or placed underground that deliver electric power over long distances from power plants to substations.

YESAB: Yukon Environmental and Socio-Economic Assessment Board

YESAA: Yukon Environmental and Socio-Economic Assessment Act

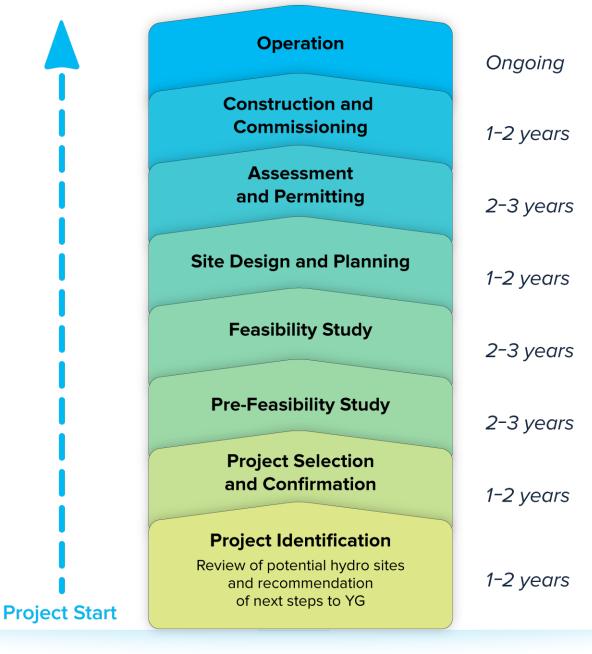

Yukon Hydroelectric Power Planning Directive: Yukon government issued 'The Directive' to Yukon Development Corporation (YDC) in 2013. It directs YDC to "plan one or more hydroelectric projects, together with supporting renewables and transmission." The directive has seven criteria for project selection.

# **HYDRO DEVELOPMENT TIMELINE**

A hydro facility is a large undertaking. It can take a minimum of 10-15 years to select, plan and build a hydro project. The chart below shows a typical development timeline for a hydro project. The timeline can shift when considering the development and exploration of several options at the same time.

# LEVELIZED COST OF ENERGY (LCOE)

Calculating a cost of energy, or a "Levelized Cost of Energy" (LCOE), provides a consistent means of economically comparing generation projects. The LCOE calculation accounts for both the energy generated, and the total capital and operating costs for a generation facility over its expected lifetime. Levelized Cost of Energy models base the valuation on net present value calculations of the time value of capital costs, operating costs, and energy outputs. For Next Generation Hydro, LCOE has been calculated two ways (Full Utilization LCOE and Forecast Utilization LCOE).

### **Full Utilization LCOE**

The Full Utilization LCOE, expressed in \$/MWh, is calculated assuming that a project is built at its maximum size and capacity, that the project generates at its maximum potential, and that all of the generated energy is consumed in a useful manner. This method does not take into account the reality of producing electricity on the Yukon's isolated grid because we cannot sell excess electricity and make use of 100% of the hydro facilities energy in periods of low demand or high supply (e.g. in the summer months).

### Forecast Utilization LCOE

The Forecast Utilization LCOE is more reflective of how a generation asset will be used over time in the Yukon and the costs associated with the Yukon's electricity use. This method does not assume that the project is built to full size immediately, and it also does not assume that the entire energy output is fully consumed. As a result, the Forecast Utilization LCOE is always higher than the Full Utilization LCOE because the cost of the generation asset must be paid for with less energy being produced.

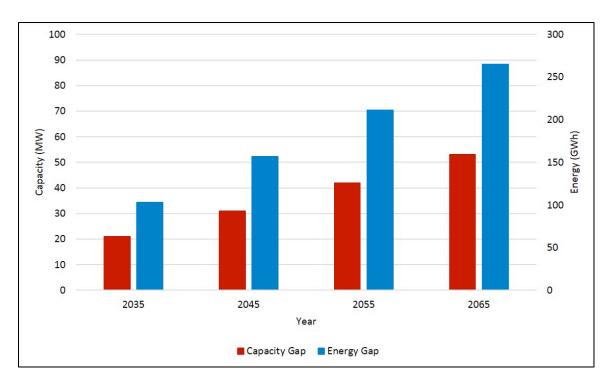

# THE YUKON CONTEXT - YUKON'S **ELECTRICITY NEEDS 20-50 YEARS** FROM TODAY

# Challenge #1 - Growing Demand for Electricity

In the Yukon we will need 62% more grid connect electricity in 50 years. According to the baseline scenario from the Yukon Electrical Energy and Capacity Need Forecast (2035-2065) Yukon will need up to an additional 265GWh of new electrical energy generation and 53MW of electrical capacity generation by 2065.

This need is expected to be driven by population growth and increases in per capita electricity use. Forecasts were put together blending historical trends and projections including continued population growth and an average number of mines in operation, based on historical figures. Today as a result of the legacy hydro assets (Whitehorse, Aishihik, and Mayo) in the Yukon we have the least expensive electricity rates in the North. Our rates are comparable to major southern cities like Edmonton and Calgary. In 2014 these clean renewable assets provided 99.6% of our energy needs.

From: Forecasted Baseline energy and Capacity Gap from Yukon Electrical Energy and Capacity Need Forecast (2035-2064)

# Challenge #2 - An Islanded Grid

The Yukon grid is a self-reliant islanded grid. We must rely on our own resources to meet our needs. On an islanded grid, we cannot sell extra electricity or buy from others when we have a shortfall as we have no transmission line connection to our neighbours. This means we must rely on energy sources that can provide dependable capacity when we need it most - in the cold dark winter.

# Challenge #3 - Winter Peak Demand

Access to affordable, reliable electricity is crucial for the safety of our citizens and the success of our businesses and communities. We must find a generation solution that can provide electricity we can depend on in our cold dark winters.

We use natural resources such as the sun, wind, water and fossil fuels to produce energy. These sources are available to us in different quantities at different times of the day month and year. For example, river flows in the Yukon are typically weakest in the winter months, as is solar energy when we need it most.

# **How Does Each Energy Source Compare?**

Not all energy sources are created equal and each generation source has benefits, challenges, risks and tradeoffs. We must consider a range of factors.

Can the generation source provide enough electrical energy to meet our territorial needs 20-50 years from today?

Does the generation source provide dependable capacity when we need it in the coldest darkest months of the year?

What are the costs of the project? How will this affect electricity rates? Is the project economically feasible?

What is the land footprint of the technology? How does it affect fish, wildlife, traditional and cultural land use and other considerations?

Is the energy source renewable or non-renewable?

# **HOW DOES EACH GENERATION SOURCE COMPARE?**

Each energy source was compared to review its ability to meet the forecasted need on a standalone basis and the cost, socio-economic and environmental effects of each technology. The table below summarizes the findings from the Providing a Context For Next Generation Hydro - Other Solutions to Meet Yukon's Long Term Energy Needs paper.

|  | Technical                            |   |  | Economic                                | Socio-<br>Economic        | Envi                             | ronmental  |

From: Providing a Context for Next Generation Hydro - Other Solutions to Meet Yukon's Long Term Energy Needs Paper

The table below describes each individual technology's ability to meet the need as a standalone resource.

| Resource          | Standalone | Rationale   |
|-------------------|------------|---|
|                   | Resource   |   |
|                   |            |   |
| Wind <sup>4</sup> | No         | The integration limit for wind (plus utility battery support) is 28 MW <sup>5</sup> in 2065 |
| Willia            | NO         | (20% of installed capacity), and this is insufficient to meet the Yukon's                   |
|                   |            | forecast energy and capacity needs. Must be combined with other                             |
|                   |            | generation types.   |
| Solar             | No         | The integration limit for solar is 14MW in 2065 (10% of installed capacity),                |
| Joiai             | NO         | and this is insufficient to meet the Yukon's forecast energy and capacity                   |
|                   |            | needs. Must be combined with other renewable generation types.                              |
| Next              | Yes        | Next Generation Hydro provides sufficient dependable winter energy and                      |
| Generation        | res        |   |
|                   |            | capacity (57MW expandable up to 90-107MW as required) to meet the                           |
| Hydro             |            | Yukon's forecast energy and capacity needs.   |
| Run-of-River      | No         | Practical limits on easily developed Run-of-River projects limit the winter                 |
| Hydro             |            | energy and capacity economically available from this resource type. On a                    |
|                   |            | standalone basis, over 80 Run-of-River projects would be required to meet                   |
|                   |            | the winter energy and capacity needs in 2065. Hence, Run-of-River hydro is                  |
|                   |            | an expensive source of winter energy and capacity.  |
| Small Hydro       | No         | Small Hydro Storage energy shape limits the winter energy and capacity                      |
| with Storage      |            | economically available from this resource type. On a standalone basis,                      |
|                   |            | approximately 14 projects would be required to meet winter energy and                       |
|                   |            | capacity needs in 2065. To reduce the overall costs Small Hydro Storage will                |
|                   |            | likely be combined with other generation types and is preferred over Run-of-                |
|                   |            | River as a source of small hydro winter energy and capacity.                                |
| Pumped            | No         | This 20MW resource is a net energy consumer; therefore it must be                           |
| Storage           |            | combined with other generation types as part of a generation portfolio.                     |
| Hydro             |            |   |
| Natural Gas       | Yes        | Natural Gas Generation provides sufficient dependable winter energy and                     |
|                   |            | capacity.   |

From: Providing a Context for Next Generation Hydro - Other Solutions to Meet Yukon's Long Term Energy Needs Paper

# **ENERGY SCENARIOS COMPARISONS**

The Putting Next Generation Hydro in Context – Other Solutions to Meet Yukon's Long Term Energy Future was developed to provide a context for Next Generation Hydro by presenting the impacts and tradeoffs of a variety of alternative supply options.

# **Scenarios**

Seven different energy alternatives were compared and then packaged into four scenarios that reflect how each of the energy sources could work together.

| Scenario  | Description   | Resources Included  |
|---|---|---|
| Scenario 1 – Natural Gas                                    | Build out natural gas generation  | Natural Gas   |
| Scenario 2 – Next<br>Generation Hydro                       | Build a single Next-Generation Hydro project  | Next Generation Hydro   |
| Scenario 3 – Renewables<br>Portfolio (No Pumped<br>Storage) | Build a combination of renewable generation resources (excluding pumped storage hydro) to satisfy energy needs. If required to satisfy residual capacity needs, add natural gas generation. | Wind (with utility scale battery), solar, run-of-river hydro, small hydro with storage and natural gas (capacity only)                  |
| Scenario 4 – Renewables<br>Portfolio with Pumped<br>Storage | Build a combination of renewable generation resources including pumped storage hydro to satisfy energy needs. If required to satisfy residual capacity needs, add natural gas generation.   | Wind (with utility scale battery), solar, run-of-river hydro, small hydro with storage, pumped storage, and natural gas (capacity only) |

All tables from Putting Next Generation Hydro in Context – Other Solutions to Meet Yukon's Long Term Energy Needs

The graphs are a visual representation of how each energy source in the scenarios contributes to meeting future energy and capacity needs.

From Putting Next Generation Hydro in Context - Other Solutions to Meet Yukon's Long Term Energy Future

# **Scenario Comparisons**

Each portfolio was compared for it's ability to meet the forecasted electricity and capacity gap, its costs, greenhouse gas emissions and land use footprint. The chart below summarizes the tradeoffs between the four scenarios.

| Scenario        | Meets Yukon Energy | Meets<br>Yukon<br>Capacity | Economic  Forecast Utilization LCOE | Socio-<br>Economic<br>Social Impact | Environ<br>2065 Land-<br>Use<br>Footprint | 2065 GHG<br>Emissions<br>(tonnes |
|-----------------|--------------------|----------------------------|-------------------------------------|-------------------------------------|---|----------------------------------|

From: Providing a Context For Next Generation Hydro - Other Solutions to Meet Yukon's Long Term Energy Needs

# TECHNICAL SITE SCREENING PROCESS

The technical team has reviewed, compared and ranked over 200 hydro sites in the Yukon to determine potential suitable sites to meet our electricity needs 20-50 years from now.

Studies from the last 60 years were reviewed and compiled in this process. The methodology below provides an overview of how the sites were short listed.

# **200 PROJECTS OF INTEREST**

# SCREEN O Reconciliation of Known Projects

Duplicate projects and projects with not enough detail of study were eliminated.

### **SCREEN 1 Fundamental Development Barrier Screen**

Projects that had the following characteristics were eliminated:

- Main stem of the Yukon River
- Urban flooding
- Projects in a National Park
- Projects smaller than 10MW
- Incorrect project type (projects that were water diversion only, storage only, or pumped storage)

# SCREEN 2 Fundamentally Uneconomic Screen

High-level project costing and energy production assumptions were used to eliminated projects that were fundamentally uneconomic. Any project expected to produce energy at a higher cost than the equivalent thermal generator (18.3¢/kWh) were screened out from further study.

# **16 PROJECTS OF INTEREST**

The 16 projects of interest were reviewed according to the four following areas.

| AREA 1 Environmental Considerations  | AREA 2 Surface / Subsurface Considerations                           | AREA 3 Constructibility Considerations   | AREA 4  Economic  Considerations                          |
|--|--|--|---|
| <ul><li>Fish Habitat</li><li>Aquatic Species<br/>at Risk</li><li>Terrestrial Species<br/>at Risk</li></ul> | Land Tenure (surface & subsurface)     First Nation Settlement Lands | <ul><li>Permafrost<br/>Classification</li><li>Terrain Hazards</li><li>Bedrock Faults</li></ul> | Value of Storage     Ability to Deliver     Winter Energy |

Based on this analysis short-listed sites were recommended to be reviewed as part of the viability study.

# 10 SHORT LISTED SITES

| RESIZING   | CASCADING  | RECONCILIATION  | SCALABILITY   |
|--|--|---|---|
| Projects were sized to match the winter energy needs identified in the forecast. | Projects were combined to see how they met the need when put together. | All sites, individual or cascading that did not meet over 95% of the winter energy needs were removed from consideration. | Remaining projects were examined to determine how each site would scale out to meet the forecasted needs over time. |

# **6 PROJECTS OF INTEREST**

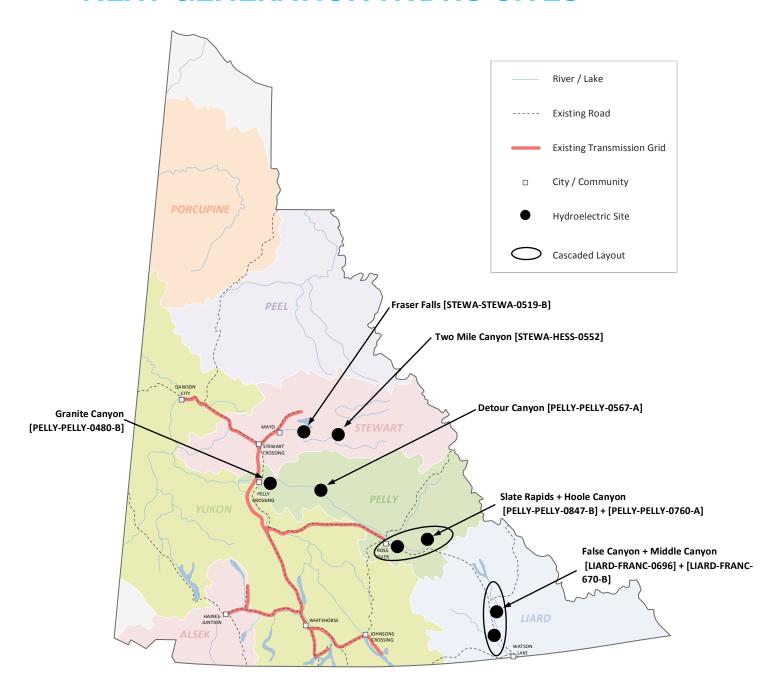

| COST  | SOCIO ECONOMIC AND ENVIRONMENTAL EFFECTS  |
|---|---|
| Capital costs and Levelalized cost of energy (LCOE) for each remaining site are calculated. High level estimates and site designs are prepared. | The potential positive and negative socio-economic and environmental effects effects of each site are considered. |

Six potential remain for consideration in the Next Generation Hydro and Transmission Viability Study.

### PROJECT DESCRIPTION

### False Canyon + Middle Canyon Run of River

is a cascade of two sites with False Canyon located upstream on the Frances River providing water storage and generation, and Middle Canyon Run of River located downstream operating as a run-of-river facility with no water storage (but a headpond needed to create head for generation purposes.)

The False Canyon project includes an approximately 65 m dam with a spillway control structure, a fish ladder, a water intake, a conveyance, a 3-unit powerhouse, trailrace structures and diversions to facilitate dewatering of the dam site during construction.

The Middle Canyon project includes an approximately 17 m dam, fish ladder, a water intake, conveyance, a 3-unit powerhouse, trailrace structure and diversions to facilitate de-watering of the dam site during construction.

# **PROJECT DESCRIPTION**

# Slate Rapids + Hoole Canyon Run of River

is a cascade of two sites with Slate Rapids located upstream on the Pelly providing water storage and generation, and Hoole Canyon run of river located downstream operating as a run-of-river facility with no water storage (but a headpond needed to create head for generation purposes.)

The **Slate Rapids** project includes an approximately 57 m dam with a spillway control structure, a fish ladder, a water intake, conveyance, a 2-unit powerhouse, trailrace structures and diversions to facilitate dewatering of the dam site during construction.

The **Hoole Canyon** run of river project includes an approximately 71 m weir dam, a fish ladder, a water intake, conveyance, a 2-unit powerhouse, trailrace structures and diversions to facilitate dewatering of the dam site during construction.

# TRANSMISSION RESULTS SUMMARY

Connecting the Yukon electrical grid to a neighbouring electrical grid offers several potential benefits. For example, with a transmission line connection, Yukon could purchase energy in times of need, and sell excess energy in times of surplus. As a result, trading with neighbours is a potential source of revenue for the territory and mitigates the risk of being stranded with excess generation supply due to overbuilding for forecast future need.

Unfortunately, connecting the Yukon grid also comes with risks and costs. Namely, any transmission line would be expensive, significant upgrades to the existing Yukon system would likely be required, and trading partners must be willing to purchase at high prices and sell at low prices to generate financial benefits.

The goal of the Transmission Logistics and Market Assessment papers was to determine the technical and economic attributes of developing a transmission line to another jurisdiction. The reports studied two potential transmission lines, one to Iskut, BC, and one to Fairbanks, Alaska. A third option connecting to Skagway, Alaska was already studied in a separate report as part of the Southeast Alaska Economic Corridor Viability Assessment.

### **Technical Assessment**

The transmission lines required to connect the Yukon to either BC or Alaska are very long and costly to build. In addition, due to the long length the transmission lines also have a relatively low carrying capacity, meaning they are not able to transfer a large amount of electricity. As a result of the high cost of interconnection and low transfer capacity the benefits of constructing must be large to justify the costs.

| Interconnection Option | <u>Description</u>   | <u>Distance</u><br>(km) | Capital<br>Cost<br>(\$M) | Potential Net Yukon Export <sup>2</sup> Capacity (MW) |
|------------------------|--|-------------------------|--------------------------|---|
| #1                     | 287 kV from Whitehorse (Takhini) to Iskut, BC                                | 763                     | \$1,710                  | 64 - 127 <sup>3</sup>                                 |
| #1A                    | Same as option 1 with Next Generation Hydro sites developed near Watson Lake | 763                     | \$1,710                  | 94 - 139 <sup>4</sup>                                 |
| #2                     | 230 kV from Aishihik to Delta Junction                                       | 662                     | \$1,325                  | 70 - 80 <sup>5</sup>                                  |

Table 1 - Transmission Interconnection Options From: Yukon - Transmission Interconnection Assessment

| <u>Interconnection</u> | <u>Description</u>   | Capital Cost per MW of Potential |
|------------------------|--|----------------------------------|
| <u>Option</u>          |  | Net Export Capacity (\$M)        |
| #1                     | Whitehorse to Iskut, BC  | \$13 - \$27                      |
| #1A                    | Whitehorse to Iskut, BC<br>(Next Generation Hydro near Watson<br>Lake) | \$12 - \$18                      |
| #2                     | Aishihik to Delta Junction   | \$16 - \$19                      |

Table 2 – Comparison Of Capital Cost Per Mw Of Net Export Capacity From: Yukon - Transmission Interconnection Assessment

# **Market Assessment**

Based on an analysis of the BC and Alaskan markets for electricity trade with the Yukon, the benefits from trade do not justify the cost of the transmission lines. Given the potential price at which we can import and export energy, the long transmission lines, relatively small Yukon demand, and low carrying capacity the transmission lines to either Alaska or BC are uneconomic.

The table below shows the anticipated export revenue that would be possible given the technical limitations of the proposed transmission lines and the anticipated sale price of electricity and compares it to the cost of building transmission as well as new generation assets needed to produce the power that could be sold.

|                           | (a)  | (b1)   | (b2) | (a) + (b1) + (b2)     |  |
|---------------------------|--|--|------|-----------------------|--|
| Interconnection<br>Option | Export Revenue<br>(Net of Import<br>Costs) (\$M) | New Transmission Costs (\$M)  New Generation Costs (\$M) |      | Net Benefits<br>(\$M) |  |
| YK-BC                     | 214  | -1310  | -379 | -1470                 |  |
| YK-Fairbanks              | 202  | -1015  | -379 | -1190                 |  |

Table 3 - Net Benefit Evaluation Of Two Interconnection Scenarios From: Yukon Transmission Value Assessment

To provide a sense of scale, the Yukon would need to export 227MW per hour, 24/7/365 for 60 years to defray the cost of the Iskut, BC transmission line (this would require 6 Whitehorse Rapids facilities to be in operation).
